Cinema

You have been hired by a Cinema company to build a Cinema website. They want to advertise the upcoming films as well as the current ones being presented on the big screen.

The website will be reading a database that contains the different films and the upcoming functions and its going to build the catalog out of that. It should showcase information such as the days and times a specific movie is going to be available.

Also the client asks to have an internal system so that they can add and remove new films into the database in an easy way. You can create this system as a web application using ASP NET MVC or using WPF applications. They should be able to add everything they need to the database so that the films will be shown on the website.

There's a total of two web applications that need to be developed. Choose the technology that suits best the need of the client, and also the tool that you feel more confident working with.

You can add posters from existing movies or create your own, the goal is to have a functional catalog, the visitors of the website shouldn't be able to do anything else than reading the catalog. The CRUD should remain in the internal system for the client.
